Yesterday, I installed (i.e., executed) a package by using the `sudo dpkg -i sudo.deb`. After that, I was curious to find out which package was installed by `sudo dpkg -i sudo.deb` as `dpkg` does not provide a way to search for installed packages by the command I know that `dpkg` provides a way to search for packages by the names: `dpkg -S` and `dpkg-query -f='${Package} ${Version} ${Architecture}\n'`. Obviously, `dpkg` is not built as an application. And `dpkg` is not an application-like software. `dpkg` is a command-line tool. And how are built-in commands stored as packages? No, the command `dpkg` could not be rebuilt as an application. We know that `dpkg` is a command-line tool. And we know that the command `dpkg` and the command `dpkg` is stored in a package. My question is, since we already know that `dpkg` is not an application, where does `dpkg` store its commands? More generally, my question is, what is the relationship between command-line tools (not build as applications) and packages? For example, what are the virtual files that located in the path `/bin` and `/sbin`? Some questions may be easy to explain. But others may not be easy to explain. A: The `dpkg -i` command does not install anything. It just makes available the package. I think, most likely, you simply installed the `.deb` package in your file system's `$PATH`. If that is the case, you can find out with the command: `dpkg-query -f='${Package} ${Version} ${Architecture}\n'`. There is no concept of "command" or a "command-line tool" in the software distribution realm. Generally, the software comes from a source and you don't need to know anything about what is contained within, it's just a matter of putting that package in your `PATH`. This works for the "softwares" in most major distros of Linux, including Ubuntu. Check here for additional information on how to add packages to your `$PATH`: [Adding Path Variable](#). Finally, if you are curious about what "packages" are, check out their wiki page:

How to port VMware vSphere 6.7.0 Build-D710.txt Is it possible to manage Docker hosts through the API? From the website, I can't find anything that says it is. Do any of you have experience doing that? I have a free private account with docker and I would like to How do I find the VMs that are running inside Docker in a given list of containers? I have several Docker containers running on the same host. Each of these containers have a list of VMs running inside of them. I'd like to be able to find the VMs that are running inside one of the containers. Q: Network Security of Akamai How is Akamai used to secure a network of websites? A: Akamai is a secure web cache. This means that they are storing your website, and making it easier for people to access it by caching the website on the their servers, when it is being requested. In order to connect to Akamai, you have a special identifier that you provide when you register, called a "key". That key is a random string of letters and numbers. When someone wants to visit your website, they first check the cache. If the site is not found, or is found but doesn't match the identifier given in the request, the request is sent to Akamai. If they can't find it there, they will cache your website at the Akamai server, and send that to the requesting person. Akamai also stores a list of known "bad" websites (and possibly "good" ones), so you can prevent your site from being added there. That way, even if someone accesses your site without connecting to Akamai (using a local web cache, or a network sniffer), it is not guaranteed they will be able to access it. I: SelfLink title: SecurityKind status: Draft source: --- Security kind allows a service account to specify the necessary privileges for the associated admission or patch permissions. ## Local representation of security kind The `security_kind` is a String value representing the Kind of the Resource. ## Examples * Role which Occ13bf012
